Does Registry Services offer any API?

A.A - 2026-10-05 - Miscellaneous tech

Registrar API

Registry Services provides a REST API that can be used as a complement to EPP and the Registrar Web. The API does not replace EPP or the Registrar Web. It is primarily intended for situations where the EPP protocol or the Registrar Web is less suitable, where certain functionality is not supported, or where there is a need to automate recurring checks.

Getting started with the Registrar API

To use the API, you need to create an API client. You can do this by logging in to the Registrar Web.

When you create an API client, a **secret** is generated and displayed only once. The secret is used to authenticate against the API and must therefore be stored securely.

You also need to specify **1–4 IP addresses** that are allowed to use the API client.

What can you do with the API?

The Registrar API can be used to, among other things:

- Retrieve a list of your domains and filter the results, for example to identify expired domains or domains that will expire within a specified number of days.
- Retrieve a list of domains that will soon be released.
- Retrieve an invoice specification for a specific invoice.

The Registrar Web also provides access to this type of information, but the API makes it easier to automate continuous and recurring checks.

Documentation

Complete technical documentation for the Registrar API is available at:
